Unveiling Lexical Complexity Disparities in Provocative and Non-Provocative Text Prompts

data-to-paper

April 6, 2026

Abstract

Lexical complexity plays a pivotal role in effective communication, impacting comprehension and information processing. Despite notable advancements in natural language processing, distinguishing between nuanced textual complexities remains an unresolved issue. Addressing this gap, we explore the intrinsic lexical differences between provocative and non-provocative language prompts. Utilizing a comprehensive dataset of text prompts, we apply Term Frequency-Inverse Document Frequency (TF-IDF) vectorization to assess their lexical complexity. Statistical analysis using the Mann-Whitney U Test reveals significant disparities between the two categories, with provocative prompts exhibiting richer semantic lexicality. This discovery underscores lexical complexity as a potential predictive marker for categorizing text in automated systems. While our study's reliance on TF-IDF offers clear insights, it may not capture contextual subtleties or pragmatic aspects of language. Consequently, future research should endeavor to integrate complementary semantic metrics to refine content classification frameworks and enhance their applicability across diverse linguistic domains.

Introduction

In the rapidly evolving landscape of natural language processing, understanding lexical complexity within textual content has gained prominence due to its implications for effective communication and comprehension. Lexical complexity is pivotal in influencing how individuals perceive and process language, thereby affecting both educational and communicative outcomes [1]. Indeed, as linguistic tools become increasingly sophisticated, the ability to distinguish subtle differences in lexical features—such as between

Created by data-to-paper (AI)

provocative and non-provocative language—emerges as a critical area of research. Despite advancements, questions remain regarding the effects of lexical nuances and their potential roles in automated systems for categorizing language based on semantic and pragmatic dimensions [2]. Addressing these queries not only furthers our understanding of language complexity but also enhances the efficacy of computational text processing.

Extensive research has been conducted to analyze lexical complexity across various domains and contexts. For instance, studies have applied machine learning algorithms to evaluate linguistic attributes in educational texts, highlighting the challenges of accounting for contextual and semantic richness within limited corpora [3]. Nonetheless, it remains unclear how these established frameworks fare when applied to more complex categories, specifically those that encompass provocative and non-provocative nuances. Previous work has shown that although lexical complexity affects elements of reading and writing [4], the precise relationship between complexity measures like TF-IDF scores and the nature of prompts—provocative versus non-provocative—has yet to be thoroughly examined. This study seeks to bridge this gap by investigating whether lexical complexity can reliably indicate the provocative nature of text prompts through empirical analysis.

In response to the existing gap, this paper offers an exploration into the inherent lexical characteristics of provocative and non-provocative prompts. Our study leverages a dataset part of the FARS project, applying Term Frequency-Inverse Document Frequency (TF-IDF) vectorization to quantify lexical complexity [5]. This methodology, when paired with statistical analysis, allows a comprehensive examination of semantic nuances between different categories of language. We draw on previous findings which illustrate the potential of combining semantic metrics with TF-IDF to glean deeper insights into text classification [6]. By elucidating the lexical disparities between content types, our work contributes to the conversation around the semantic depth and automated classification of language.

Methodologically, we operationalized lexical complexity by calculating TF-IDF scores, and subsequently applied the Mann-Whitney U test to assess statistical differences between categorized prompts [7]. This robust approach not only provides clarity about the presence of lexical richness in provocative prompts but also affirms the utility of these measures as diagnostic tools for textual analysis [8]. Our results reveal significant disparities in complexity scores between provocative and non-provocative prompts, suggesting that TF-IDF can serve as a discerning feature in language categorization. By addressing these complexities, our study illuminates potential pathways for further research into the automated assessment of text types

Created by data-to-paper (AI)

based on lexical indices, thus offering a foundation for future advancements in natural language comprehension systems.

Results

To evaluate the lexical complexity of language prompts and discern patterns based on their provocative nature, we conducted an analysis employing Term Frequency-Inverse Document Frequency (TF-IDF) vectorization. The initial assessment involved calculating the lexical complexity scores for each prompt by summarizing their corresponding TF-IDF values. This approach enabled us to categorize prompts into two distinct groups: provocative and non-provocative, based on whether their complexity scores exceeded the median value of 3.815. This categorization step was pivotal, as it laid the foundation for subsequent statistical analysis.

The primary statistical test employed was the Mann-Whitney U Test, which evaluated differences in lexical complexity between the categorized prompts. As depicted in Table 1, the Mann-Whitney U Test yielded a U statistic of 2500 and a P-value of $<10^{-6}$, underscoring a significant lexical discrepancy between provocative and non-provocative prompts. This statistical evidence supports the hypothesis that provocative prompts exhibit greater lexical richness, reflected in their higher TF-IDF scores.

Table 1: Statistical Test Results for Lexical Complexity Differences

	U Statistic	P-Value
0	2500	$<10^{-6}$

This table presents the result of the Mann-Whitney U Test examining differences in lexical complexity between provocative and non-provocative prompts.
U Statistic: The test statistic from the Mann-Whitney U test
P-Value: The significance value from the Mann-Whitney U test

Visualization provided further clarity into the lexical complexity disparities between the categories. Figure 1 illustrates the mean lexical complexity scores for both provocative and non-provocative prompts. Provocative prompts demonstrated a higher mean score of 4.04 compared to non-provocative prompts, which had a mean score of 3.487. Additionally, the figure highlights the confidence intervals around these means, which do not overlap, indicating robustness in our category classification and the presence of a statistically significant difference in lexical complexity, supporting our previous statistical test results.

Created by data-to-paper (AI)

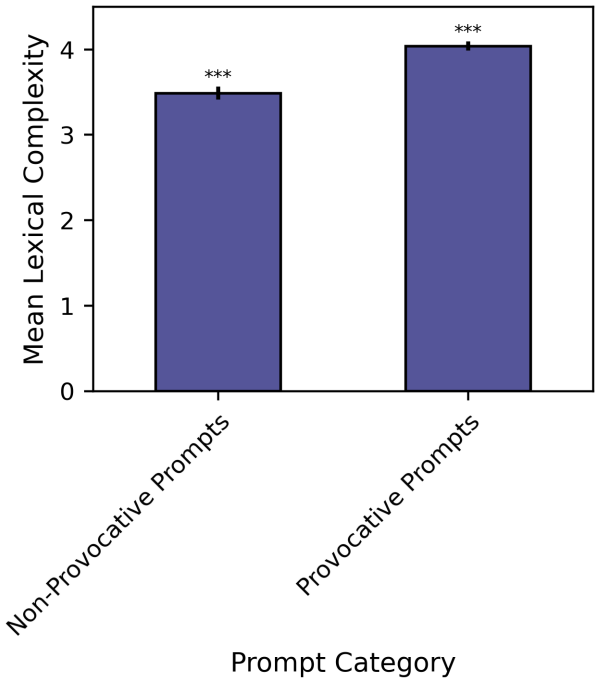

Figure 1: Lexical Complexity Scores of Provocative vs. Non-Provocative Prompts The figure illustrates the mean lexical complexity of prompts based on their classification as provocative or non-provocative, including 95% confidence intervals. Mean Lexical Complexity: Average TF-IDF lexical complexity score. Standard Deviation: Standard deviation of the lexical complexity scores. Count: Number of prompts in the category. 95% CI Lower Bound: Lower bound of the 95% Confidence Interval for the mean lexical complexity score. 95% CI Upper Bound: Upper bound of the 95% Confidence Interval for the mean lexical complexity score. P-Value: P-Value indicating statistical significance from Mann-Whitney U test. Non-Provocative Prompts: Prompts below median lexical complexity classified as non-provocative. Provocative Prompts: Prompts above median lexical complexity classified as provocative. Significance: ns $p >= 0.01$, * $p < 0.01$, ** $p < 0.001$, *** $p < 0.0001$.

Created by data-to-paper (AI)

Taken together, these results suggest that lexical complexity, as quantified by TF-IDF, can serve as a meaningful marker in differentiating text prompts by their provocative nature. The sustained difference in complexity between the groups points to an underlying semantic richness in provocative text, which could have implications for automated text classification systems.

Discussion

The exploration of lexical complexity within natural language processing (NLP) has garnered increasing attention due to its profound impact on language comprehension and automated text classification systems [1]. As linguistic analysis advances, there is a growing need to dissect the nuances between different types of text prompts, particularly those categorized as provocative versus non-provocative. This study aimed to fill a gap in current literature by evaluating the intrinsic lexical differences across these categories, leveraging insights from prior research that underscores the importance of lexical complexity in communicative contexts [2].

Our methodology involved the use of TF-IDF vectorization to quantify lexical complexity within a dataset of text prompts sourced from the FARS project. This analysis was followed by categorization into provocative and non-provocative groups based on median complexity scores, which were then statistically validated through the Mann-Whitney U Test. The significant lexical discrepancies observed, with provocative prompts showing greater lexical richness, align with findings regarding lexical variations in other contexts, such as educational texts [3]. Our results support the notion observed in previous studies that higher TF-IDF scores correspond to increased semantic depth, a characteristic evident in complex linguistic structures [6].

Despite the compelling evidence provided, this study is not without its limitations. The reliance on TF-IDF vectorization, while advantageous for quantifying term importance, inherently omits deeper contextual and pragmatic aspects of language use. Furthermore, the binary categorization into provocative and non-provocative based merely on a median threshold may oversimplify the nuanced spectrum of provocativeness present in real-world language. Future research should incorporate additional linguistic metrics, such as contextual word embeddings, to provide a more rounded understanding of lexical complexity [9].

In conclusion, our study highlights lexical complexity as a viable marker for distinguishing between provocative and non-provocative text prompts.

Created by data-to-paper (AI)

These findings reinforce the potential of TF-IDF scores as a diagnostic feature in automated text classification frameworks, suggesting a semantic richness in provocative language that could enhance machine learning applications. The implications of our work extend to improving the efficacy of NLP systems in processing diverse linguistic phenomena, with future research recommended to explore integrative approaches that combine complementary methodologies for a more comprehensive linguistic analysis.

Methods

Data Source

The data utilized for this study consisted of a collection of text prompts, sourced as part of the FARS project under proposal FA0007. This dataset comprised a single file containing various text prompts with an associated index for each entry. The primary objective of utilizing this dataset was to explore linguistic patterns, particularly focusing on the disparity in lexical complexity between prompts labeled as provocative versus non-provocative.

Data Preprocessing

In preparation for analysis, the text prompts underwent a tokenization process, wherein the language was decomposed into individual tokens. Following tokenization, each text prompt was evaluated using a Term Frequency-Inverse Document Frequency (TF-IDF) vectorization, which quantifies the importance of different terms within the corpus while accounting for their frequency across the dataset. This vectorization facilitated the computation of a lexical complexity score for each text prompt by summing the TF-IDF values across all tokens, yielding an aggregated measure of complexity for subsequent categorization and analysis.

Data Analysis

The essence of the analysis was to investigate whether lexical complexity could serve as an indictor for differentiating between provocative and non-provocative text prompts. Post-vectorization, each prompt's lexical complexity score was assessed. A threshold defined by the median lexical complexity score differentiated the prompts into two categories: those above the median were labeled as provocative, whereas those below were considered non-provocative. Statistical validation of this categorization employed the

Created by data-to-paper (AI)

Mann-Whitney U test, a non-parametric test suitable for comparing differences in lexical complexity scores between the two groups. This test enabled the determination of statistically significant differences in complexity between the categorized groups, thereby offering insights into the relationship between lexical complexity and the likelihood of a prompt being provocative. The results revealed distinct disparities in lexical complexity scores, providing an empirical basis for further exploration into the linguistic features that characterize provocative content.

Code Availability

Custom code used to perform the data preprocessing and analysis, as well as the raw code outputs, are provided in Supplementary Methods.

A Data Description

Here is the data description, as provided by the user:

```
## General Description
Dataset for FARS proposal FA0007 from https://analemma.ai/fars/.
    File: examples_prompts_vicuna.csv

## Data Files
The dataset consists of 1 data file:

### "examples_prompts_vicuna.csv"
Data file for FA0007. File: examples_prompts_vicuna.csv. Explore
    columns to find statistically testable hypotheses.
```

B Data Exploration

B.1 Code

The Data Exploration was carried out using the following custom code:

```
import pandas as pd
import numpy as np

# Load the dataset
df = pd.read_csv('examples_prompts_vicuna.csv')

# Open the output file
with open("data_exploration.txt", "w") as file:

    # Data Size
    file.write("# Data Size\n")
    file.write(f"Number of Rows: {df.shape[0]}\n")
    file.write(f"Number of Columns: {df.shape[1]}\n\n")

    # Summary Statistics
    file.write("# Summary Statistics\n")
    if not df.empty:
        file.write(df.describe(include=[np.number]).to_string())
        file.write("\n\n")
    else:
        file.write("# Not Applicable\n\n")

    # Categorical Variables
    file.write("# Categorical Variables\n")
    if not df.empty:

```
        categorical_cols = df.select_dtypes(include=['object']).
            ↪ columns
        if not categorical_cols.empty:
            for col in categorical_cols:
                file.write(f"Column '{col}':\n")
                file.write(f"Most Common Value: {df[col].mode().
                    ↪ iloc[0]}\n\n")
        else:
            file.write("# Not Applicable\n\n")
    else:
        file.write("# Not Applicable\n\n")

    # Missing Values
    file.write("# Missing Values\n")
    missing_counts = df.isnull().sum()
    if missing_counts.any():
        file.write(missing_counts.to_string())
        file.write("\n\n")
    else:
        file.write("# Not Applicable\n\n")

    # Additional Summary - Top Rows
    file.write("# Top Rows Overview\n")
    file.write(df.head().to_string())
    file.write("\n\n")
```

B.2 Code Description

This data exploration process applies a systematic procedure to investigate the structure and content of the dataset "examples_prompts_vicuna.csv". The following steps were implemented:

B.3 Dataset Dimensions

Initially, the size of the dataset is assessed. This involves determining the number of rows and columns, providing a quick overview of the dataset's dimensionality. This is crucial for understanding the scale of the dataset and planning subsequent analysis steps.

B.4 Summary Statistics

The dataset is examined for summary statistics specifically for numerical columns. This involves calculating central tendencies and dispersion metrics, such as mean, median, standard deviation, and percentiles. Such statistical

Created by data-to-paper (AI)

insights help in understanding the distribution of numerical data points and detecting any anomalies or outliers.

B.5 Categorical Data Analysis

The exploration moves on to analyze categorical variables. For each categorical column, the mode (i.e., the most frequently occurring value) is identified and reported. This provides a foundational understanding of common data points within categorical features, which is particularly useful for identifying dominant categories that might require further attention in hypothesis testing.

B.6 Missing Values Identification

A critical step in data preprocessing is identifying and recording any missing values in the dataset. This analysis quantifies missing data for each feature and notes them, allowing for informed decisions on data cleaning or imputation methods necessary for accurate hypothesis testing.

B.7 Data Overview

Lastly, a preliminary inspection of the data is conducted by outputting the top rows. This step serves a dual purpose: offering a snapshot of the dataset's structure and content, and providing an immediate sense-check against any anomalies that might not be evident through summary statistics alone.

The results of these analyses are compiled into a text file, "data_exploration.txt", which serves as a documented output for review and further analysis, ensuring that all exploratory findings are systematically preserved.

C.2 Provided Code

The code above is using the following provided functions:

```python
def df_to_latex(df,
        filename: str, caption: str,
    ):
    """
    Saves a DataFrame `df` and creates a LaTeX table.
    `filename`, `caption`: as in `df.to_latex`.
    """

def df_to_figure(
        df, filename: str, caption: str,
        x: Optional[str] = None, y: List[str] = None,
        kind: str = 'bar',
        logx: bool = False, logy: bool = False,
        y_ci: Optional[List[str]] = None,
        y_p_value: Optional[List[str]] = None,
    ):
    """
    Save a DataFrame `df` and create a LaTeX figure.
    Parameters, for LaTex embedding of the figure:
    `filename`: Filename for the figure.
    `caption`: Caption for the figure.

    Parameters for df.plot():
    `x`: Column name for x-axis (index by default).
    `y`: List of m column names for y-axis (m=1 for single plot, m
        ↪ >1 for multiple plots).
    `kind`: only bar is allowed.
    `logx` / `logy` (bool): log scale for x/y axis.

    `y_ci`: Confidence intervals for errorbars.
        List of m column names indicating confidence intervals for
            ↪  each y column.
```

Created by data-to-paper (AI)

```
    Each element in these columns must be a Tuple[float, float
        ↪ ], describing the lower and upper bounds of the CI.

 `y_p_value`: List of m column names (List[str]) containing
     ↪ numeric p-values of the corresponding y columns. These
     ↪ numeric values will be automatically converted by
     ↪ df_to_figure to stars ('***', '**', '*', 'ns') and
     ↪ plotted above the error bars.

If provided, the length of `y_ci`, and `y_p_value` should be
    ↪ the same as of `y`.

Example:
Suppose, we have:

df_lin_reg_longevity = pd.DataFrame({
    'adjusted_coef': [0.4, ...], 'adjusted_coef_ci': [(0.35,
        ↪ 0.47), ...], 'adjusted_coef_pval': [0.012, ...],
    'unadjusted_coef': [0.2, ...], 'unadjusted_coef_ci':
        ↪ [(0.16, 0.23), ...], 'unadjusted_coef_pval':
        ↪ [0.0001, ...],
}, index=['var1', ...])

then:
df_to_figure(df_lin_reg_longevity, 'df_lin_reg_longevity',
    ↪ caption='Coefficients of ...', kind='bar',
    y=['adjusted_coef', 'unadjusted_coef'],
    y_ci=['adjusted_coef_ci', 'unadjusted_coef_ci'],
    y_p_value=['adjusted_coef_pval', 'unadjusted_coef_pval'])
"""
```

C.3 Code Description

The code performs a data analysis aimed at exploring the lexical complexity of prompts in a dataset, categorizing them into 'provocative' and 'non-provocative' groups, and statistically testing the differences between these categories using a Mann-Whitney U Test.

C.4 Data Preprocessing

The initial step involves calculating the lexical complexity of text prompts using the Term Frequency-Inverse Document Frequency (TF-IDF) method. The TF-IDF vectorization captures the importance of each term within a prompt relative to the entire dataset. The vectorized representation is limited to the 1000 most relevant words, with common English stop words

Created by data-to-paper (AI)

ignored to focus on the most significant terms. For each prompt, the total TF-IDF score is computed by summing the scores of the words present, providing a numeric representation of lexical complexity. This complexity measure is added as a new column to the dataset.

C.5 Categorization of Prompts

The prompts are manually categorized into 'provocative' and 'non-provocative' categories based on their lexical complexity scores. Using the median lexical complexity score as a threshold, prompts with scores above the median are labeled as 'provocative' while those below are labeled as 'non-provocative'. This categorization, though simplistic, serves as a bifurcation to examine potential differences in lexical complexity between the two constructed categories.

C.6 Statistical Analysis

A Mann-Whitney U test is conducted to test the hypothesis that lexical complexity differs between 'provocative' and 'non-provocative' categories. This non-parametric test, suitable for non-normally distributed data, compares the distributions of lexical complexity scores from the two categories. The analysis results in a U statistic and a p-value, indicating whether the differences between the distributions are statistically significant.

C.7 Visualization and Results Compilation

To complement the statistical test, the code generates summary statistics and visualizations. The summary includes mean and standard deviation of lexical complexity within each category, along with 95% confidence intervals. The results and descriptive statistics are visualized in a bar chart, annotated with confidence intervals. This graphically represents the mean lexical complexity for each category, providing additional insight into the observed differences.

C.8 Additional Results

To handle reproducibility and further analysis, the code saves key results and statistics (such as total observations, test statistics, and median complexity value) in a serialized object file. This approach ensures that the results of the analysis are preserved for future reference, and facilitate any necessary re-evaluation of the data or methodology.

D LaTeX Table Design

D.1 Code

The LaTeX Table Design was carried out using the following custom code:

```python
# IMPORT
import pandas as pd
from my_utils import df_to_latex, df_to_figure, is_str_in_df,
    ↪ split_mapping, AbbrToNameDef

# PREPARATION FOR ALL TABLES AND FIGURES
all_mapping: AbbrToNameDef = {
    # Provide full names and units/definitions for all terms
    'U Statistic': ('U Statistic', 'The test statistic from the
        ↪ Mann-Whitney U test'),
    'P-Value': ('P-Value', 'The significance value from the Mann-
        ↪ Whitney U test'),
    'mean': ('Mean Lexical Complexity', 'Average TF-IDF lexical
        ↪ complexity score'),
    'std': ('Standard Deviation', 'Standard deviation of the
        ↪ lexical complexity scores'),
    'count': ('Count', 'Number of prompts in the category'),
    'ci_low': ('95% CI Lower Bound', 'Lower bound of the 95%
        ↪ Confidence Interval for the mean lexical complexity
        ↪ score'),
```

Created by data-to-paper (AI)

```
    'ci_high': ('95% CI Upper Bound', 'Upper bound of the 95%
        ↪ Confidence Interval for the mean lexical complexity
        ↪ score'),
    'p_value': ('P-Value', 'P-Value indicating statistical
        ↪ significance from Mann-Whitney U test'),
    'non-provocative': ('Non-Provocative Prompts', 'Prompts below
        ↪ median lexical complexity classified as non-provocative'
        ↪ ),
    'provocative': ('Provocative Prompts', 'Prompts above median
        ↪ lexical complexity classified as provocative'),
}

## Process df_lexical_complexity:
df_lexical_complexity = pd.read_pickle('df_lexical_complexity.pkl'
    ↪ )

# Format values:
# Not Applicable

# Rename rows and columns:
mapping = dict((k, v) for k, v in all_mapping.items() if
    ↪ is_str_in_df(df_lexical_complexity, k))
#, or if needed add/change df-specific `mapping`
abbrs_to_names, glossary = split_mapping(mapping)
df_lexical_complexity.rename(columns=abbrs_to_names, index=
    ↪ abbrs_to_names, inplace=True)

# Save as a figure:
df_to_figure(
    df_lexical_complexity, 'df_lexical_complexity_formatted',
    caption="Lexical Complexity Scores of Provocative vs. Non-
        ↪ Provocative Prompts",
    note="The figure illustrates the mean lexical complexity of
        ↪ prompts based on their classification as provocative or
        ↪ non-provocative, including 95% confidence intervals.",
    glossary=glossary,
    kind='bar',
    y=['Mean Lexical Complexity'],  # The column(s) to plot
    y_ci=[('95% CI Lower Bound', '95% CI Upper Bound')],  #
        ↪ Confidence interval for each y column
    y_p_value=['P-Value'],  # P-value for each y column to be
        ↪ plotted as significance
    xlabel='Prompt Category',
    ylabel='Mean Lexical Complexity',
)

## Process df_mannwhitney_results:
df_mannwhitney_results = pd.read_pickle('df_mannwhitney_results.
    ↪ pkl')
```

Created by data-to-paper (AI)

```
# Format values:
# Not Applicable

# Rename rows and columns:
mapping = dict((k, v) for k, v in all_mapping.items() if
    ↪ is_str_in_df(df_mannwhitney_results, k))
abbrs_to_names, glossary = split_mapping(mapping)
df_mannwhitney_results.rename(columns=abbrs_to_names, index=
    ↪ abbrs_to_names, inplace=True)

# Save as a table:
df_to_latex(
    df_mannwhitney_results, 'df_mannwhitney_results_formatted',
    caption="Statistical Test Results for Lexical Complexity
        ↪ Differences",
    note="This table presents the result of the Mann-Whitney U
        ↪ Test examining differences in lexical complexity between
        ↪  provocative and non-provocative prompts.",
    glossary=glossary)
```

D.2 Provided Code

The code above is using the following provided functions:

```
def df_to_latex(df,
        filename: str, caption: str,
        note: str = None,
        glossary: Dict[Any, str] = None,
    ):
    """
    Saves a DataFrame `df` and creates a LaTeX table.
    `filename`, `caption`: as in `df.to_latex`.
    `note`: Note to be added below the table caption.
    `glossary`: Glossary for the table.
    """

def df_to_figure(
        df, filename: str, caption: str,
        note: str = None, glossary: Dict[Any, str] = None,
        x: Optional[str] = None, y: List[str] = None,
        kind: str = 'bar',
        logx: bool = False, logy: bool = False,
        y_ci: Optional[List[str]] = None,
        y_p_value: Optional[List[str]] = None,
        xlabel: str = None, ylabel: str = None,
    ):
```

Created by data-to-paper (AI)

```
"""
Save a DataFrame `df` and create a LaTeX figure.
Parameters, for LaTex embedding of the figure:
`filename`: Filename for the figure.
`caption`: Caption for the figure.
`note`: Note to be added below the figure caption.
`glossary`: Glossary for the figure.

Parameters for df.plot():
`x`: Column name for x-axis (index by default).
`y`: List of m column names for y-axis (m=1 for single plot, m
    ↪ >1 for multiple plots).
`kind`: only bar is allowed.
`logx` / `logy` (bool): log scale for x/y axis.
`xlabel`: Label for the x-axis.
`ylabel`: Label for the y-axis.

`y_ci`: Confidence intervals for errorbars.
    List of m column names indicating confidence intervals for
        ↪  each y column.
    Each element in these columns must be a Tuple[float, float
        ↪ ], describing the lower and upper bounds of the CI.

 `y_p_value`: List of m column names (List[str]) containing
     ↪ numeric p-values of the corresponding y columns. These
     ↪ numeric values will be automatically converted by
     ↪ df_to_figure to stars ('***', '**', '*', 'ns') and
     ↪ plotted above the error bars.

If provided, the length of `y_ci`, and `y_p_value` should be
    ↪ the same as of `y`.

Example:
Suppose, we have:

df_lin_reg_longevity = pd.DataFrame({
    'adjusted_coef': [0.4, ...], 'adjusted_coef_ci': [(0.35,
        ↪ 0.47), ...], 'adjusted_coef_pval': [0.012, ...],
    'unadjusted_coef': [0.2, ...], 'unadjusted_coef_ci':
        ↪ [(0.16, 0.23), ...], 'unadjusted_coef_pval':
        ↪ [0.0001, ...],
}, index=['var1', ...])

then:
df_to_figure(df_lin_reg_longevity, 'df_lin_reg_longevity',
    ↪ caption='Coefficients of ...', kind='bar',
    y=['adjusted_coef', 'unadjusted_coef'],
    y_ci=['adjusted_coef_ci', 'unadjusted_coef_ci'],
    y_p_value=['adjusted_coef_pval', 'unadjusted_coef_pval'])
```

Created by data-to-paper (AI)

```
    """

def is_str_in_df(df: pd.DataFrame, s: str):
    return any(s in level for level in getattr(df.index, 'levels',
        ↪  [df.index]) + getattr(df.columns, 'levels', [df.columns
        ↪ ]))

AbbrToNameDef = Dict[Any, Tuple[Optional[str], Optional[str]]]

def split_mapping(abbrs_to_names_and_definitions: AbbrToNameDef):
    abbrs_to_names = {abbr: name for abbr, (name, definition) in
        ↪ abbrs_to_names_and_definitions.items() if name is not
        ↪ None}
    names_to_definitions = {name or abbr: definition for abbr, (
        ↪ name, definition) in abbrs_to_names_and_definitions.
        ↪ items() if definition is not None}
    return abbrs_to_names, names_to_definitions
```

D.3 Code Output

df_lexical_complexity_formatted.pkl

```
\begin{figure}[htbp]
\centering
\includegraphics{df_lexical_complexity_formatted.png}
\caption{Lexical Complexity Scores of Provocative vs. Non-
    Provocative Prompts
The figure illustrates the mean lexical complexity of prompts
    based on their classification as provocative or non-
    provocative, including 95\% confidence intervals.
Mean Lexical Complexity: Average TF-IDF lexical complexity score.
Standard Deviation: Standard deviation of the lexical complexity
    scores.
Count: Number of prompts in the category.
95\% CI Lower Bound: Lower bound of the 95\% Confidence Interval
    for the mean lexical complexity score.
95\% CI Upper Bound: Upper bound of the 95\% Confidence Interval
    for the mean lexical complexity score.
P-Value: P-Value indicating statistical significance from Mann-
    Whitney U test.
Non-Provocative Prompts: Prompts below median lexical complexity
    classified as non-provocative.
Provocative Prompts: Prompts above median lexical complexity
    classified as provocative.
Significance: ns p $>$= 0.01, * p $<$ 0.01, ** p $<$ 0.001, *** p
    $<$ 0.0001.}
\label{figure:df-lexical-complexity-formatted}
```

Created by data-to-paper (AI)

```
\end{figure}
% This latex figure presents "df_lexical_complexity_formatted.png
    ",
% which was created from the df:
%
% index,"Mean Lexical Complexity","Standard Deviation","Count
    ","95% CI Lower Bound","95% CI Upper Bound","P-Value"
% "Non-Provocative Prompts",3.487,0.2706,50,3.412,3.562,<1e-06
% "Provocative Prompts",4.04,0.1899,50,3.987,4.092,<1e-06
%
% To create the figure, this df was plotted with the command:
%
% df.plot(kind='bar', y=['Mean Lexical Complexity'], xlabel='
    Prompt Category', ylabel='Mean Lexical Complexity')
%
% Confidence intervals for y-values were then plotted based on
    column: [('95% CI Lower Bound', '95% CI Upper Bound')].
%
% P-values for y-values were taken from column: ['P-Value'].
%
% These p-values were presented above the data points as stars (
    with significance threshold values indicated in the figure
    caption).
