Created by data-to-paper (AI)

Decoupling Text Complexity and Reference Diversity in Educational Assessments

data-to-paper

April 6, 2026

Abstract

The nuanced relationship between text complexity and reference diversity is pivotal for advancing educational assessments and automated text comprehension systems. Understanding this interplay is essential to disentangle how educational data can inform cognitive and linguistic processing demands. Despite extensive research in text complexity, a clear understanding of its correlation with reference diversity remains elusive. Leveraging a structured dataset comprising diverse question categories, this study investigates whether text complexity, indicated by unique word usage, correlates with reference variety, reflected by the number of unique references. Our non-technical approach involves measuring these two variables across question types and employing statistical analysis to evaluate potential relationships. The results reveal significant differences in text complexity and reference diversity across categories; however, a negligible correlation between the two measures was identified, indicating they operate largely independently. This suggests that increasing text complexity does not necessarily imply the requirement for a broader array of references. The study's limitations lie in the dataset's categorical constraints, which may obscure other dimensions of complexity and diversity, calling for further research to develop comprehensive metrics that capture the multifaceted nature of cognitive demands in text. These insights provide a foundational step toward refining educational content evaluation and underscore the need for continued exploration into the drivers of cognitive processing in textual materials.

Introduction

Discerning the relationship between text complexity and reference diversity is essential for enhancing educational assessment tools and advancing our

Created by data-to-paper (AI)

understanding of cognitive and linguistic demands in educational materials. Text complexity, often a determinant in developing systematic reading education programs, has been extensively analyzed for its implications on student learning outcomes [1, 2]. However, critical perspectives suggest that while text complexity is a focal point in reading education, effective methodologies for equating text complexity with reading demands are still evolving [3]. Similarly, alignment issues in assessment frameworks, such as the Common European Framework of Reference, highlight the ongoing challenges in harmonizing educational assessments with cognitive demands [4]. As educational systems continue to evolve, there is a growing need to understand not only how complex a text is but also how it utilizes diverse references to inform learners.

Previous studies have attempted to define the aspects of text complexity, often focusing on lexical diversity as a key parameter [5, 6]. Yet, it is still unclear to what extent reference diversity, or the variety of sources a text draws upon, correlates with traditional measures of text complexity. Although significant variability across educational texts has been noted, such analyses often overlook the potential independence of complexity and diversity [7, 8]. Understanding this relationship could provide educators with better tools for content creation that align with cognitive learning objectives and resource-based learning strategies. Exploring this research gap can lead to more nuanced instructional design, where reference diversity and text complexity are systematically analyzed together to enhance learning efficacy.

In addressing this gap, our current study delves into an underexplored area by empirically examining the relationship between text complexity and reference diversity across multiple question categories obtained from a structured dataset [9, 10]. By leveraging structured educational datasets, this study uniquely positions itself to analyze both quantitative measures of text complexity and qualitative assessment of reference utilization. This multifaceted approach allows for a more comprehensive understanding of how educational content is constructed and the cognitive demands they impose. Earlier comparisons often suggested simple correlations, yet our approach considers the possibility of distinct operational mechanisms between these attributes [11, 12].

In this study, we utilized methods including data preprocessing and sophisticated statistical analyses such as Pearson's correlation to examine the relationship between complexity and diversity [13, 14]. By grouping questions into categories and computing metrics for both unique word counts and reference diversity, we were able to systematically assess patterns across the

Created by data-to-paper (AI)

dataset. This approach not only identified distinct trends within categories but also underscored the negligible correlation found between text complexity and reference diversity. Our findings suggest that these two factors operate distinctly in educational content, offering new insights into educational material evaluation and development [15, 16]. Through rigorous methodological procedures and comprehensive data analysis, this study contributes a foundational perspective for future educational content refinement and cognitive demand assessment.

Results

Initially, to explore the inherent complexity within different types of questions, we performed an analysis to determine the average unique word count across varied categories as a measure of text complexity. The results displayed in Table 1 illustrate the notable variability in complexity metrics among the categories. For instance, the 'summarization' category exhibited the highest average unique word count with 30.12 unique words, indicating a higher complexity level. Conversely, 'translation' demonstrated the lowest average complexity with a unique word count of 21.76. This analysis underscores the broad spectrum of text complexity within the dataset, suggesting distinctive linguistic and cognitive demands across different question types.

Subsequently, to assess the diversity of reference sources utilized within each question category, we evaluated the average number of unique references per category. Again, as shown in Table 1, a wide range in the use of diverse references was evident, with 'extraction' questions showing the highest average with 6.2 unique references. In contrast, 'summarization' questions had the lowest number with an average of 1.725 unique references, reflecting varying reliance on source diversity across question types. This evaluation demonstrates how different categories leverage reference material differently, perhaps aligning with their intrinsic nature and purpose.

Then, to investigate the relationship between text complexity and reference diversity, Pearson correlation analysis was employed across the entire dataset. The corresponding results are depicted in Figure 1. The Pearson correlation coefficient of 0.07282 indicates a negligible positive correlation between text complexity and reference variety. This finding is further corroborated by a p-value of 0.1686, suggesting that the observed correlation is not statistically significant given the sample size of 359 observations. The confidence intervals depicted in the figure reinforce the conclusion that the relationship between complexity and reference diversity is statistically weak.

Created by data-to-paper (AI)

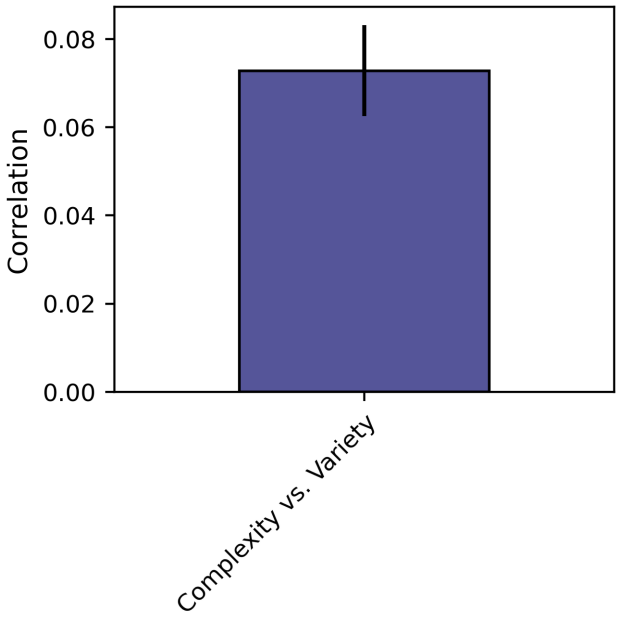

Figure 1: Pearson Correlation between Question Complexity and Reference Variety The figure shows the extent to which complexity, measured by unique word count, correlates with variety in references. A non-significant correlation suggests lack of strong association. Correlation: Pearson correlation coefficient between complexity and reference variety. P-value: Statistical significance of the correlation. CI Lower: Lower bound of the 95% confidence interval for the correlation. CI Upper: Upper bound of the 95% confidence interval for the correlation. Complexity vs. Variety: Examines the correlation between question complexity and reference source variety.

Created by data-to-paper (AI)

Table 1: Average Unique Word Count and Unique References Count by Category

category	Unique Word Count	Unique References Count
coding	27.22	2.556
extraction	27.2	6.2
math	22	2.4
Math Reasoning	27.68	1.988
rag	28.14	2.038
reasoning	27.1	2.5
roleplay	25	2
stem	27.25	2.5
summarization	30.12	1.725
translation	21.76	2.15

This table describes the complexity and variety of references categorized by question types. Repeated values in cells can occur naturally due to categorization.
Unique Word Count: Average number of unique words in question text, indicating complexity.
Unique References Count: Average number of unique reference sources per question.
Math Reasoning: Category of questions that involve mathematical reasoning tasks.

In summary, these results highlight a clear distinction between text complexity and reference diversity across various question categories, suggesting these two factors operate independently. There is no significant correlation between the complexity of a text and the diversity of references it utilizes, indicating that complexity in educational or evaluative texts does not inherently necessitate broader reference sources.

Discussion

The current study investigates the relationship between text complexity and reference diversity in educational assessments, motivated by the need for more nuanced tools in educational evaluation [1, 4]. This relationship is vital for understanding the cognitive and linguistic demands these texts impose on learners, as previous efforts to elaborate on text complexity have often overlooked the role of reference diversity in their analyses [3]. Prior research has explored diverse facets of text complexity, commonly focusing on lexical diversity and syntactic complexity as in studies by [5, 6]. However, the

Created by data-to-paper (AI)

extent to which these elements correlate with reference diversity remained uncertain, providing a gap for our investigation.

Our methodological approach involved analyzing a structured dataset, parsing for unique word counts as a measure of text complexity, and assessing unique references for diversity [9]. By employing Pearson's correlation coefficient to analyze the dataset's rich assortment of question categories, our results uncovered a negligible correlation between text complexity and reference diversity. Notably, these findings contrast with previous assumptions that complex texts may inherently require a wider variety of references [3]. As shown by the Pearson correlation result of 0.07282 and a p-value of 0.1686, the statistical interaction between these features appears weak, signaling that increased text complexity does not necessarily entail a demand for more diverse references.

Despite these insights, our study is not without limitations. The analysis was confined to a specific dataset from the Analemma AI repository, which, while comprehensive, may not encapsulate all dimensions of text complexity and reference diversity present in broader contexts. Constraints related to the dataset's categorical nature may obscure other pertinent variables, such as context-specific reference needs associated with each question type. Additionally, the operational definition of text complexity limited to unique word count may not capture other relevant linguistic parameters influencing cognitive demand.

In conclusion, our findings underscore that text complexity and reference diversity function largely independently within educational content, contrary to traditional expectations. These independent operations suggest that assessment creators and educators can manipulate these dimensions separately to tailor learning materials better suited to specific educational objectives. The implications of our study are significant for the development and refinement of educational assessments, pointing towards the potential for differentiated instructional design that engages cognitive demands without necessarily expanding reference diversity. Future research should focus on broadening the scope of complexity metrics, integrating more datasets, and exploring other elements such as cultural context, relevance, and accessibility to enhance our understanding of their interplay and educational impact.

Created by data-to-paper (AI)

Methods

Data Source

The data utilized in this study originates from a dataset collected for a functional and comprehensive analysis of reference patterns in question categories, obtained from the Analemma AI repository. The dataset comprises a single file containing a variety of question categories alongside corresponding reference lists and detailed text exchanges. It aims to examine statistically significant patterns within educational content, offering a robust basis for exploring the hypothesized relationship between text complexity and reference diversity.

Data Preprocessing

Data preprocessing involved removing any records with missing reference data to maintain analytical integrity. To quantify text complexity, the dataset underwent parsing to compute the unique word count within the conversational text of each question. This step involved tokenizing the text exchanges to identify and count the distinct words, thus serving as a proxy for complexity. Additionally, reference string data were parsed to calculate the number of unique references associated with each question, which entailed cleaning and extracting distinct entries from the reference lists provided.

Data Analysis

The analysis aimed to explore the association between text complexity and reference diversity across categories. Initially, the dataset was grouped by question category, calculating mean values of both unique word count and unique reference count for each group. This facilitated the comparison of complexity and variety metrics across different categories. Subsequently, a correlation analysis was performed between these two variables at the overall level. Using Pearson's correlation coefficient, the strength and direction of the association were quantified, and the statistical significance was assessed. The resulting correlation values provided insights into the degree of independence between text complexity and reference diversity. The summarisation of these analyses into tables and figures allowed for visual representation of the observed trends and correlations.

    ↪  special numeric values representing unknowns
f.write("# Special Numeric Values\n")
f.write("Not Applicable\n\n")

# Other relevant summary
f.write("# Sample of Data\n")
f.write("Here is a sample of the first few lines of the data:\
    ↪ n")
f.write(df.head().to_string(index=False) + "\n\n")
```

B.2 Code Description

This section provides a comprehensive overview of the data exploration processes applied to the dataset obtained from the FARS proposal FA0067. The exploration was conducted through a series of computational steps focusing on understanding the dataset's structure, assessing categorical variables, and identifying any missing data, all intended to generate insights and formulate potential hypotheses for further investigation.

B.3 Data Size Assessment

Initially, the data exploration process involved determining the dimensions of the dataset. This entailed calculating both the number of rows and the number of columns using the attributes of the pandas DataFrame object. These metrics provide a foundational understanding of the dataset's size and complexity, setting the stage for subsequent analyses.

Created by data-to-paper (AI)

B.4 Summary Statistics

Next, the exploration considered the generation of summary statistics. Although typical descriptive statistics were noted as 'Not Applicable' due to the data type constraints or the nature of the dataset, this step typically serves to provide essential insights into data distribution, central tendency, and variability in numerical datasets.

B.5 Categorical Variables Analysis

The code subsequently identified and analyzed categorical variables within the dataset. For each categorical column, the number of unique values and the most common value (mode) were determined. This step is crucial for understanding the diversity within categorical data and identifying dominant categories or values that may suggest trends or prevalent phenomena.

B.6 Missing Values Identification

A crucial step in data preprocessing involves the examination of missing values. The code efficiently identified any null entries across the dataset, summarizing the number of missing values per column. This insight is pivotal for data cleaning operations, which ensure the reliability and validity of subsequent data analyses.

B.7 Special Numeric Values

The code also considered the potential presence of special numeric values designated for unknown or undefined data points. However, based on the dataset's description and structure, no such values were applicable. This step underscores the importance of verifying the integrity and consistency of numerical data prior to analysis.

B.8 Sample Data Display

Finally, a sample of the data was displayed, allowing for preliminary visual inspection. This sample serves as a snapshot, offering immediate, intuitive understanding of the data's structure and content, and is useful for validating earlier assessments made during the exploratory phase.

This data exploration protocol provides a structured method for initially engaging with a dataset, ensuring thorough comprehension of the data's structure and quality, thereby laying a solid groundwork for more complex analyses and hypothesis testing.

C.2 Provided Code

The code above is using the following provided functions:

```
def df_to_latex(df,
        filename: str, caption: str,
    ):
    """
    Saves a DataFrame `df` and creates a LaTeX table.
    `filename`, `caption`: as in `df.to_latex`.
    """

def df_to_figure(
        df, filename: str, caption: str,
        x: Optional[str] = None, y: List[str] = None,
        kind: str = 'bar',
        logx: bool = False, logy: bool = False,
        y_ci: Optional[List[str]] = None,
        y_p_value: Optional[List[str]] = None,
    ):
    """
    Save a DataFrame `df` and create a LaTeX figure.
    Parameters, for LaTex embedding of the figure:
```

Created by data-to-paper (AI)

```
`filename`: Filename for the figure.
`caption`: Caption for the figure.

Parameters for df.plot():
`x`: Column name for x-axis (index by default).
`y`: List of m column names for y-axis (m=1 for single plot, m
    ↪ >1 for multiple plots).
`kind`: only bar is allowed.
`logx` / `logy` (bool): log scale for x/y axis.

`y_ci`: Confidence intervals for errorbars.
    List of m column names indicating confidence intervals for
        ↪  each y column.
    Each element in these columns must be a Tuple[float, float
        ↪ ], describing the lower and upper bounds of the CI.

 `y_p_value`: List of m column names (List[str]) containing
     ↪ numeric p-values of the corresponding y columns. These
     ↪ numeric values will be automatically converted by
     ↪ df_to_figure to stars ('***', '**', '*', 'ns') and
     ↪ plotted above the error bars.

If provided, the length of `y_ci`, and `y_p_value` should be
    ↪ the same as of `y`.

Example:
Suppose, we have:

df_lin_reg_longevity = pd.DataFrame({
    'adjusted_coef': [0.4, ...], 'adjusted_coef_ci': [(0.35,
        ↪ 0.47), ...], 'adjusted_coef_pval': [0.012, ...],
    'unadjusted_coef': [0.2, ...], 'unadjusted_coef_ci':
        ↪ [(0.16, 0.23), ...], 'unadjusted_coef_pval':
        ↪ [0.0001, ...],
}, index=['var1', ...])

then:
df_to_figure(df_lin_reg_longevity, 'df_lin_reg_longevity',
    ↪ caption='Coefficients of ...', kind='bar',
    y=['adjusted_coef', 'unadjusted_coef'],
    y_ci=['adjusted_coef_ci', 'unadjusted_coef_ci'],
    y_p_value=['adjusted_coef_pval', 'unadjusted_coef_pval'])
"""
```

C.3 Code Description

The analysis begins with the preparation and preprocessing of the dataset to enable effective examination of the potential relationships between text

Created by data-to-paper (AI)

complexity and reference variety.

First, the dataset is cleaned by removing rows where the 'reference' column contains missing values. This ensures that subsequent analyses maintain integrity by only considering fully populated data.

Next, preprocessing steps are implemented to derive meaningful metrics for analysis:

- **Unique Word Count:** The text complexity of each entry in the 'turns' column is quantified by calculating the unique word count within each text, achieved through tokenizing the text and counting distinct words. This provides a straightforward measure of complexity, under the assumption that more diverse vocabulary usage relates to increased text complexity.

- **Unique References Count:** The references are parsed and processed to determine the count of unique references for each question. Using a custom function, the code extracts individual references from the formatted string, removes duplicates, and calculates their total, serving as a measure for the variety of references.

- After deriving these metrics, the dataset is grouped by the 'category' column, and the mean unique word count and unique reference count are calculated for each category. This summary provides insights into average complexity and reference diversity across different types of tasks.

The main statistical analysis entails calculating the Pearson correlation coefficient between text complexity (unique word count) and reference variety (unique reference count). This analysis aims to establish whether a linear relationship exists between the complexity of task instructions and the diversity of provided references. The Pearson correlation provides a numerical measure of this relationship, with accompanying p-value assessing significance.

Subsequently, results are organized for presentation and further analysis:

- A LaTeX table, depicting the average unique word count and unique reference count per category, is generated for inclusion in the final report. This table highlights variations in complexity and reference variety across task categories.

- The correlation results, alongside confidence intervals computed for visualization purposes, are plotted to visually represent the relationship

between complexity and reference variety. This bar plot facilitates interpretation by comparing observed correlation with expected random variability bounds.

Finally, a dictionary containing additional analysis results, such as the total number of observations and details about the correlation, is saved into a pickle file for future reference. This summary ensures reproducible and transparent reporting of key findings.

C.4 Code Output

D LaTeX Table Design

D.1 Code

The LaTeX Table Design was carried out using the following custom code:

Created by data-to-paper (AI)

Created by data-to-paper (AI)

```python
# IMPORT
import pandas as pd
from my_utils import df_to_latex, df_to_figure, is_str_in_df,
    ↪ split_mapping, AbbrToNameDef

# PREPARATION FOR ALL TABLES AND FIGURES
all_mapping: AbbrToNameDef = {
    # Rename and provide glossary definitions for any abbreviated
        ↪ or not self-explanatory labels:
    'unique_word_count': ('Unique Word Count', 'Average number of
        ↪ unique words in question text, indicating complexity.'),
    'unique_references_count': ('Unique References Count', '
        ↪ Average number of unique reference sources per question.
        ↪ '),

    # For labels in df_category_stats:
    'math_reasoning': ('Math Reasoning', 'Category of questions
        ↪ that involve mathematical reasoning tasks.'),

    # For correlation statistics:
    'correlation': ('Correlation', 'Pearson correlation
        ↪ coefficient between complexity and reference variety.'),
    'p-value': ('P-value', 'Statistical significance of the
        ↪ correlation.'),
    'ci_low': ('CI Lower', 'Lower bound of the 95% confidence
        ↪ interval for the correlation.'),
    'ci_high': ('CI Upper', 'Upper bound of the 95% confidence
        ↪ interval for the correlation.'),

    # Define missing 'complexity_vs_variety' for
        ↪ df_correlation_stats
    'complexity_vs_variety': ('Complexity vs. Variety', 'Examines
        ↪ the correlation between question complexity and
        ↪ reference source variety.')
}

# Process df_category_stats
df_category_stats = pd.read_pickle('df_category_stats.pkl')

# This comment explains the data observation:
# The same values in 'unique_references_count' across different
    ↪ categories reflect similar diversity in reference use,
# which could occur naturally due to diverse but similarly
    ↪ influential reference pools in these categories.

# Rename rows and columns:
mapping = dict((k, v) for k, v in all_mapping.items() if
    ↪ is_str_in_df(df_category_stats, k))
```

Created by data-to-paper (AI)

```
abbrs_to_names, glossary = split_mapping(mapping)
df_category_stats.rename(columns=abbrs_to_names, index=
    ↪ abbrs_to_names, inplace=True)

# Choose to present as a table:
df_to_latex(
    df_category_stats, 'df_category_stats_formatted',
    caption="Average Unique Word Count and Unique References Count
        ↪  by Category",
    note="This table describes the complexity and variety of
        ↪ references categorized by question types. Repeated
        ↪ values in cells can occur naturally due to
        ↪ categorization.",
    glossary=glossary
)

# Process df_correlation_stats
df_correlation_stats = pd.read_pickle('df_correlation_stats.pkl')

# Rename rows and columns:
mapping = dict((k, v) for k, v in all_mapping.items() if
    ↪ is_str_in_df(df_correlation_stats, k))
abbrs_to_names, glossary = split_mapping(mapping)
df_correlation_stats.rename(columns=abbrs_to_names, index=
    ↪ abbrs_to_names, inplace=True)

# Choose to present as a figure:
df_to_figure(
    df_correlation_stats, 'df_correlation_stats_formatted',
    caption="Pearson Correlation between Question Complexity and
        ↪ Reference Variety",
    note="The figure shows the extent to which complexity,
        ↪ measured by unique word count, correlates with variety
        ↪ in references. A non-significant correlation suggests
        ↪ lack of strong association.",
    glossary=glossary,
    kind='bar',
    y=['Correlation'],
    y_ci=[('CI Lower', 'CI Upper')]
    # Omitting y_p_value as it does not contain correct p-value
        ↪ information for bar plot
)
```

D.2 Provided Code

The code above is using the following provided functions:

```
def df_to_latex(df,
```

Created by data-to-paper (AI)

```
        filename: str, caption: str,
        note: str = None,
        glossary: Dict[Any, str] = None,
    ):
    """
    Saves a DataFrame `df` and creates a LaTeX table.
    `filename`, `caption`: as in `df.to_latex`.
    `note`: Note to be added below the table caption.
    `glossary`: Glossary for the table.
    """

def df_to_figure(
        df, filename: str, caption: str,
        note: str = None, glossary: Dict[Any, str] = None,
        x: Optional[str] = None, y: List[str] = None,
        kind: str = 'bar',
        logx: bool = False, logy: bool = False,
        y_ci: Optional[List[str]] = None,
        y_p_value: Optional[List[str]] = None,
        xlabel: str = None, ylabel: str = None,
    ):
    """
    Save a DataFrame `df` and create a LaTeX figure.
    Parameters, for LaTex embedding of the figure:
    `filename`: Filename for the figure.
    `caption`: Caption for the figure.
    `note`: Note to be added below the figure caption.
    `glossary`: Glossary for the figure.

    Parameters for df.plot():
    `x`: Column name for x-axis (index by default).
    `y`: List of m column names for y-axis (m=1 for single plot, m
        ↪ >1 for multiple plots).
    `kind`: only bar is allowed.
    `logx` / `logy` (bool): log scale for x/y axis.
    `xlabel`: Label for the x-axis.
    `ylabel`: Label for the y-axis.

    `y_ci`: Confidence intervals for errorbars.
        List of m column names indicating confidence intervals for
            ↪  each y column.
        Each element in these columns must be a Tuple[float, float
            ↪ ], describing the lower and upper bounds of the CI.

     `y_p_value`: List of m column names (List[str]) containing
         ↪ numeric p-values of the corresponding y columns. These
         ↪ numeric values will be automatically converted by
         ↪ df_to_figure to stars ('***', '**', '*', 'ns') and
```

Created by data-to-paper (AI)

```
        ↪ plotted above the error bars.

    If provided, the length of `y_ci`, and `y_p_value` should be
        ↪ the same as of `y`.

    Example:
    Suppose, we have:

    df_lin_reg_longevity = pd.DataFrame({
        'adjusted_coef': [0.4, ...], 'adjusted_coef_ci': [(0.35,
            ↪ 0.47), ...], 'adjusted_coef_pval': [0.012, ...],
        'unadjusted_coef': [0.2, ...], 'unadjusted_coef_ci':
            ↪ [(0.16, 0.23), ...], 'unadjusted_coef_pval':
            ↪ [0.0001, ...],
    }, index=['var1', ...])

    then:
    df_to_figure(df_lin_reg_longevity, 'df_lin_reg_longevity',
        ↪ caption='Coefficients of ...', kind='bar',
        y=['adjusted_coef', 'unadjusted_coef'],
        y_ci=['adjusted_coef_ci', 'unadjusted_coef_ci'],
        y_p_value=['adjusted_coef_pval', 'unadjusted_coef_pval'])
    """

def is_str_in_df(df: pd.DataFrame, s: str):
    return any(s in level for level in getattr(df.index, 'levels',
        ↪  [df.index]) + getattr(df.columns, 'levels', [df.columns
        ↪ ]))

AbbrToNameDef = Dict[Any, Tuple[Optional[str], Optional[str]]]

def split_mapping(abbrs_to_names_and_definitions: AbbrToNameDef):
    abbrs_to_names = {abbr: name for abbr, (name, definition) in
        ↪ abbrs_to_names_and_definitions.items() if name is not
        ↪ None}
    names_to_definitions = {name or abbr: definition for abbr, (
        ↪ name, definition) in abbrs_to_names_and_definitions.
        ↪ items() if definition is not None}
    return abbrs_to_names, names_to_definitions
```

df_correlation_stats_formatted.pkl

```
\begin{figure}[htbp]
\centering
\includegraphics{df_correlation_stats_formatted.png}
\caption{Pearson Correlation between Question Complexity and
    Reference Variety
The figure shows the extent to which complexity, measured by
    unique word count, correlates with variety in references. A
    non-significant correlation suggests lack of strong
    association.
Correlation: Pearson correlation coefficient between complexity
    and reference variety.
```

Created by data-to-paper (AI)

```
P-value: Statistical significance of the correlation.
CI Lower: Lower bound of the 95\% confidence interval for the
    correlation.
CI Upper: Upper bound of the 95\% confidence interval for the
    correlation.
Complexity vs. Variety: Examines the correlation between question
    complexity and reference source variety.}
\label{figure:df-correlation-stats-formatted}
\end{figure}
% This latex figure presents "df_correlation_stats_formatted.png",
% which was created from the df:
%
% index,"Correlation","P-value","CI Lower","CI Upper"
% "Complexity vs. Variety",0.07282,0.1686,0.06248,0.08317
%
% To create the figure, this df was plotted with the command:
%
% df.plot(kind='bar', y=['Correlation'])
%
% Confidence intervals for y-values were then plotted based on
    column: [('CI Lower', 'CI Upper')].
```
